Decision_Tree

Vinoth Aryan Nagabosshanam March 24, 2017

Decision Trees

We will have a look at the Carseats data using the tree package in R, as in the lab in the book. We create a binary response variable High (for high sales), and we include it in the same dataframe.

```
library(ISLR)

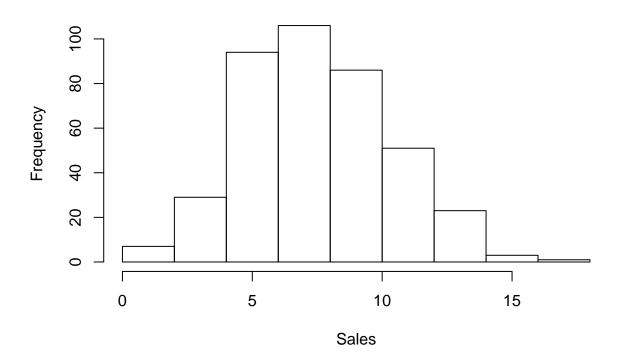

## Warning: package 'ISLR' was built under R version 3.3.3

library(tree)

## Warning: package 'tree' was built under R version 3.3.3

attach(Carseats)
hist(Sales)
```

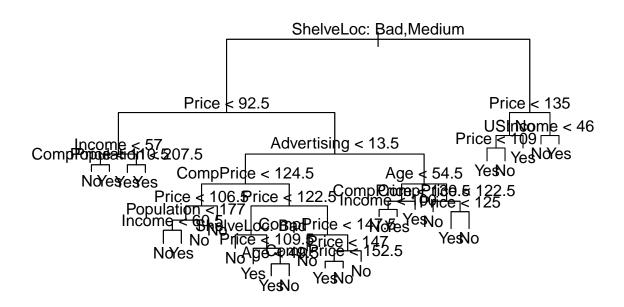

Histogram of Sales

```
High=ifelse(Sales<=8,"No","Yes")
Carseats=data.frame(Carseats, High)</pre>
```

Now we fit a tree to these data, and summarize and plot it. Notice that we have to *exclude* Sales from the right-hand side of the formula, because the response is derived from it.

```
tree.carseats=tree(High~.-Sales,data=Carseats)
summary(tree.carseats)
##
## Classification tree:
## tree(formula = High ~ . - Sales, data = Carseats)
## Variables actually used in tree construction:
## [1] "ShelveLoc"
                                                  "CompPrice"
                                                                "Population"
                    "Price"
                                   "Income"
                                    "US"
## [6] "Advertising" "Age"
## Number of terminal nodes: 27
## Residual mean deviance: 0.4575 = 170.7 / 373
## Misclassification error rate: 0.09 = 36 / 400
plot(tree.carseats)
text(tree.carseats,pretty=0)
```

For a detailed summary of the tree, print it:

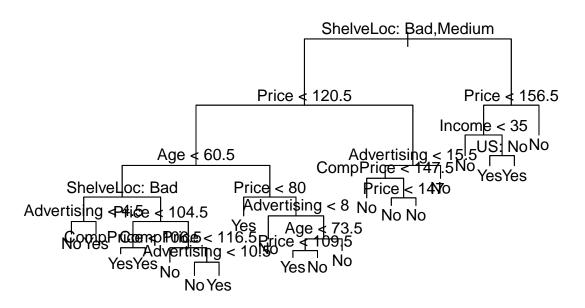

```
tree.carseats
```

```
## node), split, n, deviance, yval, (yprob)

##
```

Lets create a training and test set (250,150) split of the 400 observations, grow the tree on the training set, and evaluate its performance on the test set.

```
set.seed(1011)
train=sample(1:nrow(Carseats),250)
tree.carseats=tree(High~.-Sales,Carseats,subset=train)
```

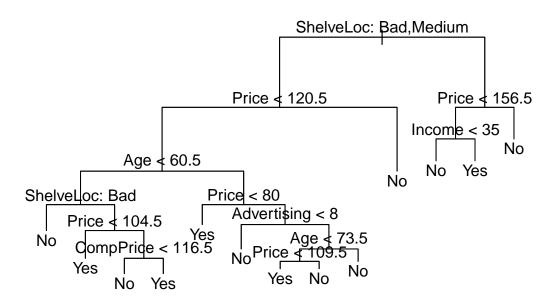

```
tree.pred=predict(tree.carseats, Carseats[-train,], type="class")
with(Carseats[-train,],table(tree.pred,High))
##
            High
## tree.pred No Yes
##
         No
            72 27
##
         Yes 18
                33
(72+33)/150
## [1] 0.7
This tree was grown to full depth, and might be too variable. We now use CV to prune it.
cv.carseats=cv.tree(tree.carseats,FUN=prune.misclass)
cv.carseats
## $size
##
   [1] 20 14 13 10 9 7 6 5 2 1
##
## $dev
##
    [1]
        65 65 57 57 59
                             64 64
                                    59
                                        78 104
##
## $k
                 0.000000 1.000000 1.333333 2.000000 2.500000 4.000000
##
    [1]
             -Inf
        5.000000 9.000000 31.000000
##
   [8]
```

```
##
## $method
## [1] "misclass"
##
attr(,"class")
## [1] "prune" "tree.sequence"
plot(cv.carseats)
```

```
prune.carseats=prune.misclass(tree.carseats,best=13)
plot(prune.carseats);text(prune.carseats,pretty=0)
```

Now lets evaluate this pruned tree on the test data.

```
tree.pred=predict(prune.carseats, Carseats[-train,], type="class")
with(Carseats[-train,], table(tree.pred, High))

## High
## tree.pred No Yes
## No 72 28
## Yes 18 32

(72+32)/150
```

[1] 0.6933333

It has done about the same as our original tree. So pruning did not hurt us wrt misclassification errors, and gave us a simpler tree.
